* For beginners, I recommend that you just follow the tutorials and not worry about theory yet. You want to practice and get your hands dirty learning. With a little patience, you will learn Photoshop as if you were a professional. A good tip is to copy a tutorial and experiment with it in Photoshop. Write down any problems you encounter, then go back to the tutorial and find a solution. Once you're comfortable with Photoshop's basic editing techniques, you can move on to more advanced editing. You will need to understand how layers work before you can understand the Photoshop palette. ## The Photoshop Palette The palette is where you perform most of the image manipulation, including adjusting and applying filters to images. It is where you create your own adjustments. You control how the image is enhanced through one of Photoshop's 28 tools. These tools include Crop, Combine, Drawing, Find & Replace, Filter, Levels, Adjustment, Dodge & Burn, Exposure, Color, and others. You can also use the keyboard shortcuts to apply the tools, or you can use the icons in the Layers palette for the same effects. Selecting tools can be a tad tricky to get a handle on. You can use the keyboard shortcuts or icons instead and learn how to use Photoshop's tools as you go along. You will learn much faster with the former.

The present invention relates to a new and distinctive soybean variety, designated SD53445 which has been the result of years of careful breeding and selection as part of a soybean breeding program. There are numerous steps in the development of any novel, desirable plant germplasm. Plant breeding begins with the analysis and definition of problems and weaknesses of the current germplasm, the establishment of program goals, and the definition of specific breeding objectives. The next step is selection of germplasm that possess the traits to meet the program goals. The goal is to combine in a single variety an improved combination of desirable traits from the parental germplasm. These important traits may include but are not limited to higher seed yield, resistance to diseases and insects, tolerance to drought and heat, and better agronomic qualities. These processes, which lead to the final step of marketing and distribution, can take from six to twelve years from the time the first cross is made. Therefore, development of new varieties is a time-consuming process that requires precise forward planning, efficient use of resources, and a minimum of changes in direction. Soybean (*Glycine max*), is an important and valuable field crop. Thus, a continuing goal of soybean breeders is to develop stable, high yielding soybean varieties that are agronomically sound. The reasons for this goal are obviously to maximize the amount of grain produced on the land used and to supply food for both animals and humans. To accomplish this goal, the soybean breeder must select and develop soybean plants that have the traits that result in superior varieties. Pioneer soybean research staff create over 500,000 potential new varieties each year. Of those new varieties, less than 50 and more commonly less than 25 are actually selected for commercial use. The soybean is the world's leading source of vegetable oil and protein meal. The oil extracted from soybeans is used for cooking oil, margarine, and salad dressings. Soybean oil is composed of saturated, monounsaturated and polyunsaturated fatty acids. It has a typical composition of 11% palmitic, 4% stearic, 25% oleic, 50% linoleic and 9% linolenic fatty acid content ("Economic Implications of Modified Soybean Traits Summary Report", Iowa Soybean Promotion Board & American Soybean Association Special Report 92S, May 1990). Changes in fatty acid composition for improved oxidative stability and nutrition are also important traits

Histological changes in the reproductive tract of female mice treated with cyclosporin A from the day of birth to day 50 of life. The aim of this study was to examine whether the immunosuppressive agent cyclosporin A (CsA) could induce histological changes in the female reproductive tract, as it has been reported in males. For this purpose, day-old female mice were daily injected with CsA from the day of birth until day 50, a period equivalent to 4-5 weeks for a 20-day-old mouse. Mice were sacrificed at the end of the treatment, then the ovaries, oviducts and uteri were examined histologically. We observed that a moderate number of immunocompetent cells were destroyed in the epithelium of the uterus, oviducts and ovaries. Moreover, we also noted that the epithelium appeared to be thickened throughout the entire reproductive tract of treated mice. On the contrary, immune cells in the lumen of the oviducts and ovarian tubes were normal. These findings indicate that, as reported in males, CsA induces changes in the female reproductive tract. Radio frequency identification (RFID) communication systems, such as "UHF RFID" systems, are known in the art. Such systems typically incorporate UHF RFID communication devices (e.g., tags, readers, and the like), or reader devices, which are capable of

communicating data back to a base station or host device via a UHF RFID antenna array. In such systems, an interrogator or reader may be utilized to communicate with tags attached to a plurality of items, wherein the tags are capable of communicating information back to the reader. Typically, the tags are attached to the items by a machine, such as an adhesive printer, a label maker, or the like, and as such may be referred to as “adhesive-based” tags or “adhesive-based” devices. Many of the UHF RFID systems utilize a type of “soft” tag based on adhesive surfaces rather than hard tags. A UHF RFID system employing soft tags typically has at least two tags to be applied to items to be identified. In such systems, at least two tags are applied to at least two portions of items to be identified to form a tag pair. It is then assumed that each tag on the tag pair has some type of internal history of each tag as the
