I am making a project that requires a rebar, but most of the range is not suitable. Can I use some that has a range that is not suitable and change it? eg. A: No. If the rebar is for a specific range, you would need the rebar for that specific range. If it was made for a range but you are using it as an exclusive, you'll either have to find a rebar for a different range and hope no one realizes the difference, or use a custom rebar for the set range you need. NOTE: I'm not saying there is not a way to do this, just that it is not in general possible without the manufacturer giving you permission to use the rebar outside of it's standard range. Q: Understanding the requirements for doing a static analysis on a checked-in, deployed, production codebase I have a project of some 9000 lines of code. We are generating static code analysis tooling on this project, and we have generated a report. The report tells us that we are lacking such and such checks. It's a good thing, because it should be so. So, in order to make the client happy, we have been going through and doing code audits on the whole codebase, to find out where we miss those checks. We have identified two primary places where the codebase is not as good as it could be. We have fixed and performed the needed changes in them and included them in our report. But the project is already deployed on production, so we have been doing audits on production as well as on the code repository. We are approaching the end of the project. We need to get all the reports out the door as soon as possible. What's the best way to approach this? What tests and what metrics should we use? Should we be doing static analysis on the production code as well as the development code? Any help on this would be appreciated. A: You need to see whether the results from a static analysis of the production code will be relevant for the code's quality in a real environment. For example, if the quality of the code being analyzed is equivalent to that of the code in question, you have no
